Demo Title(s)	PaaS – BlockChain Cloud Service (BCS)

Oracle Blockchain Cloud Service

Oracle Blockchain Cloud Service is a new offering that is part of Oracle's comprehensive platform-as-a service (PaaS) portfolio. Delivered by the world's most scalable, distributed transaction processing platform provider, Oracle Blockchain Cloud Service is the most comprehensive distributed ledger cloud platform. A comprehensive distributed ledger cloud platform to provision Blockchain networks, join other organizations, and deploy & run smart contracts to update and query the ledger. Reliably share data and conduct trusted transactions with suppliers, banks, and other trade partners through integration with existing or new cloud-based or on-premises applications.

Overview

End-to-End Application Flow

This HandsOn Lab showcases the end to end flow of working with an existing Oracle Blockchain Cloud Service (OBCS) network and execute transactions between 3 parties as well as querying the ledger. Both will be shown using the OBCS REST API and via sample Business Applications.

- Execute transactions on the Blockchain
- Query the Ledger
- Use sample apps to access the Blockchain network

S.No.	Action	Description	
Chap	Chapter 1: Recap and starting point		
1.00 Whether you come from the previous lab 'Creating a Blockchain network' or starting fresh with this lab, you'll find a work based on Hyperledger Fabric that will run in the Oracle Cloud on 3 instances (Blockchain Network participants) of Oracle Blockchain Cloud Service (OABCS). This network simulates the business network between a Car Manufacturer (Detroit/Dealers (Sam & Jude, Participants). At the end of the previous lab and as a starting point for this lab the Blockchain Network with some dummy transactions to enable this lab which is all about interacting with the Blockchain Network through the OABCS.		will run in the Oracle Cloud on 3 instances (Blockchain Network participants) of Oracle Autonomous S). This network simulates the business network between a Car Manufacturer (DetroitAuto, Founder) and 2 Car s). At the end of the previous lab and as a starting point for this lab the Blockchain Network has been populated

		detroitautoorderer	
		DetroitAuto-peer1.dauto	
		jude.channel	
		JudeDealer-peer0.jude.com	
		JudeDealer-peer1.jude.com	
	Now, we are going to work on this network and create transactions that will be recorded as blocks in to our Blockchain network. The OBCS can be accessed via the REST API (something that Oracle added on top of HLF) or, in a real-world scenario through business apps interacting via REST with OBCS. We will begin with the REST API and some sample queries. You can work against the ledger (Query, Invocation) by making REST calls using the terminal or apps like Postman. What you can do against the ledger is defined in the instantiated chaincode.		
1.01	ChainCode / Smart Contract	This chapter will provide an overview about the 'logic' of our Blockchain Network. This logic is defined in the ChainCode/SmartContract that is running on the Channels where the Blockchain Network participants are communicating with each other.	

S.No.	Action	Description	
		Chaincode is defining what types of data are written dutransactions are executed and validating the conditions and manages ledger state through transactions submit business logic agreed to by members of the network, scontract.	s under which they should be run. Chaincode initializes ted by applications. A chaincode typically handles
1.02	Looking into the ChainCode we can find the following Methods and Arguments which are defined for our carTrace sample: NOTE: A full list of available Methods and Arguments can	Method initVehiclePart (add a car part)	Arguments part id: string assembler: string assembly time: timestamp owner: string recall status: boolean recall time: timestamp
	be seen in the carTrace.go file on the VM in the /Documents folder.	initVehicle (add a car)	vehicle id: string manufacturer: string vehicle name: string assembly time: timestamp airbag serial: string owner: string recall status: Boolean recall time: timestamp
		transferVehiclePart (transfer ownership)	part id: string current owner: string new owner: string
		transferVehicle (transfer ownership)	vehicle id: string current owner: string new owner: string
		readVehiclePart (read records)	vehicle id: string part id: string
		getHistoryForRecord (read records)	part id: string
		deleteVehiclePart (delete records)	part id: string
		setPartRecallState (recall a part)	part id: string

		status: Boolean
1.03	OABCS REST API	One of the improvements of Oracle Autonomous Blockchain Cloud Service on top of the Open Source Hyperledger Fabric is the availability of a comprehensive REST API tat provides a standard and easy interaction with the chaincode and Blockchain Network and therefore enables a quick integration of business apps with the Blockchain Cloud Service. The REST API is available through a REST proxy on each Blockchain Network participant's instance. ORACLE Autonomous Blockchain Cloud Service Console Dashboard Network Nodes Channels Chaincodes Developer Tools

1.04	Blockchain transactions	You can use the terminal window or any preferred REST tooling like Postman calling the gateway. More info can be found in the documentation: https://docs.oracle.com/en/cloud/paas/blockchain-cloud/user/developing-applications-using-rest-apis.html During the creation of the Blockchain Network, the ledger has been populated with some sample transaction. You can see the key/value pairs in the table:

	Congratulation		
	You completed Chapter 1		

Chap	Chapter 2: Working with the Blockchain – REST API basics		
2.00	In this chapter we will begin with the REST API and try some sample queries against our Blockchain Network. You can work against the ledger (Query, Invocation) by making REST calls using the terminal or apps like Postman. What you can do against the ledger is defined in the instantiated chaincode (see previous chapter).		
2.01	The default syntax for working on the Command Line looks like the following:	Curl -H "Content-type:application/json" -X POST http://yourRESTProxy_endpoint:PORT/bcsgw/rest/v1/transaction/invocation -d '{	
	NOTE: The method and arguments depend on your choice of method. See previous section. You could either do an Invocation or Query.	"channel":" <channel_name>",</channel_name>	
2.02	Let's do a query against the ledger for a specific car part. 1. Open a terminal window 2. Enter the following sequence at the cursor position. 3. Hit 'Return' to submit the command. 4. The expected outcome should look like this (formatted for better readability).	curl -H "Content-type:application/json" -X POST http://localhost:3100/bcsgw/rest/v1/transaction/query -d '{"channel":"samchannel","chaincode":"carTrace","method":"readVehiclePart","args":["abg1234"]}' {"returnCode":"Success","info":null,"result":{ "payload": "{\"docType\":\"vehiclePart\", \"serialNumber\":\"abg1234\", \"assembler\":\"panama-parts\", \"assemblyDate\":1502688979, \"name\":\"airbag 2020\", \"owner\":\"detroit auto\", \"recall\":false, \"recallDate\":1502688979}", "encode":"UTF-8"}}	

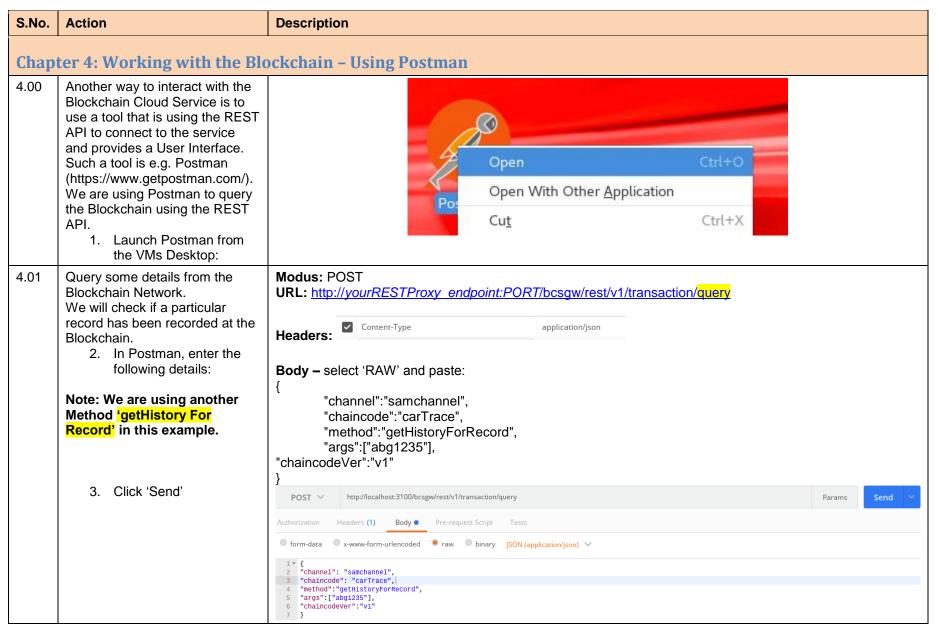

ORACLE' Global Sales Engineering

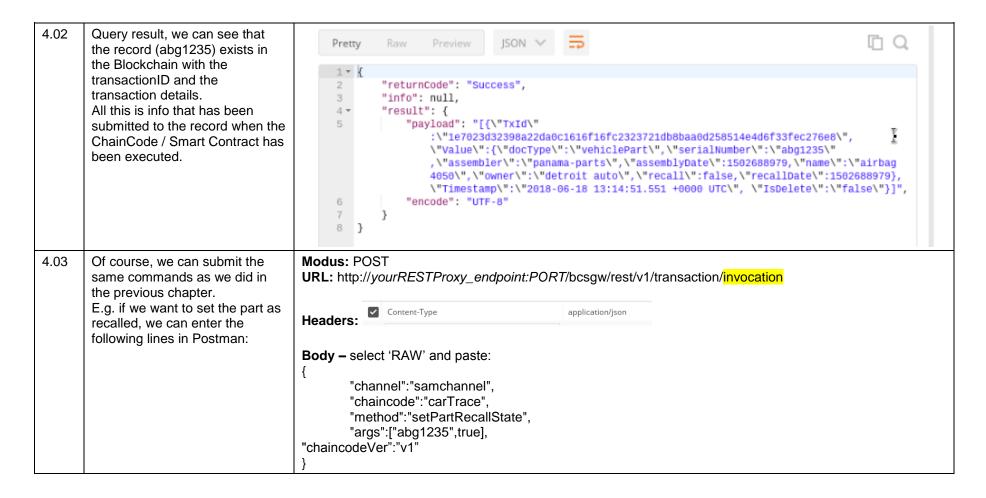

Chap	Chapter 3: Working with the Blockchain – REST API making changes		
3.00	Now we want to make use of a feature in our Chaincode / SmartContract. Assuming that the Car manufacturer would like to recall a specific part delivered to the dealer. This part (record) must be changed and marked as recalled. As we cannot change the Blockchain, we have to add a new block where we append the existing information with the recall.		
3.01	Now we are going to "invoke" a method on the "carTrace" chaincode that will effectively mark a particular part as recalled via a REST call. 1. Type the following sequence into your terminal window. 2. Hit 'Return' to submit the command.	curl -H "Content-type:application/json" -X POST http://127.0.0.1:3100/bcsgw/rest/v1/transaction/invocation -d '{"channel":"samchannel","chaincode":"carTrace","method":"setPartRecallState","args":["abg1234",true]}'	
3.02	3. The expected outcome should look like this (formatted for better readability). NOTE: The REST API is giving back the result of the command. As we have done an Invocation instead of a Query, we are just getting 'Success' back.	{"returnCode":"Success","info":null,"result":null,"txid":"583f3ca55b9f2860875b8978e386611b476892c348 440a248f07e98dbdad419d"} bcsdemo@oabcs-vm:~	
3.03	In order to verify the change (recall), let's execute the query from above again:	curl -H "Content-type:application/json" -X POST http://localhost:3100/bcsgw/rest/v1/transaction/query -d '{"channel":"samchannel","chaincode":"carTrace","method":"readVehiclePart","args":["abg1234"]}'	
3.04		{"returnCode":"Success","info":null,"result": {"payload":" {\"docType\":\"vehiclePart\", \"serialNumber\":\"abg1234\", \"assembler\":\"panama-parts\", \"assemblyDate\":1502688979, \"name\":\"airbag 2020\", \"owner\":\"detroit auto\",	

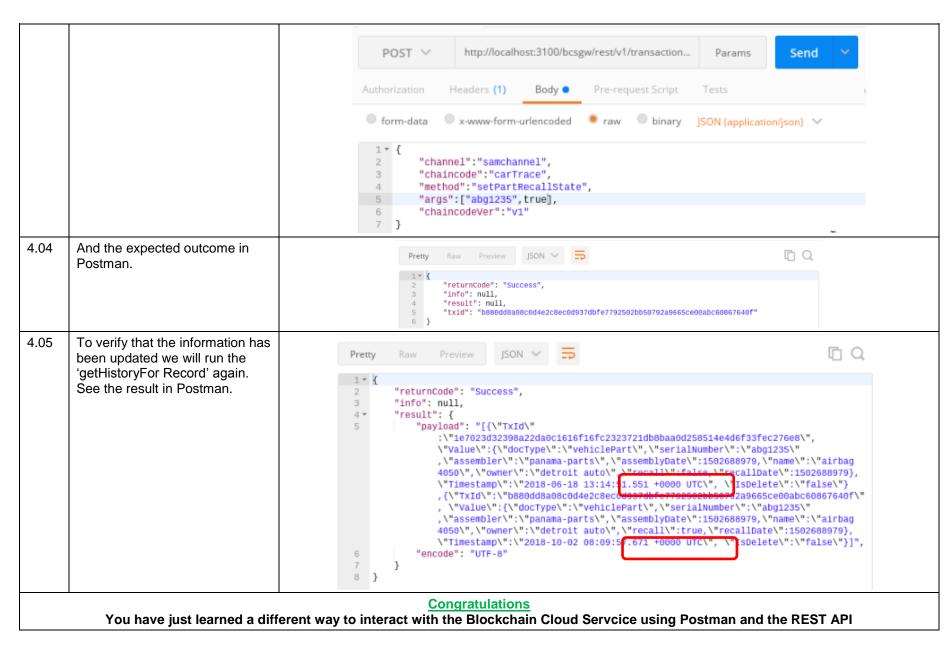

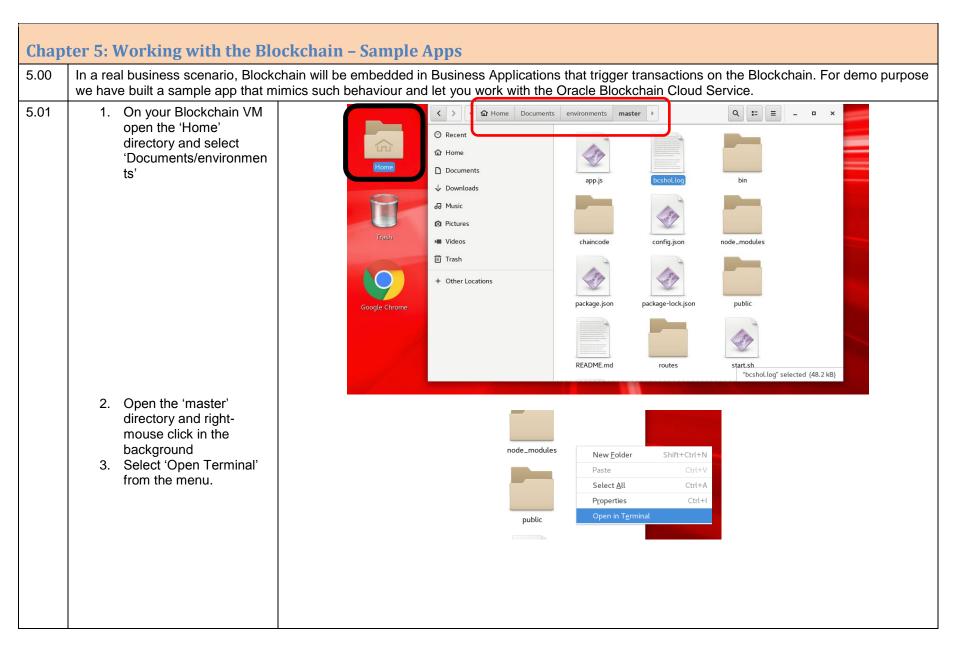

ChainCode/SmartContract.
